Stakeholder Representative
Cystic Fibrosis (CF) is the most common fatal genetic condition in Canada, affecting over 4,300 Canadians (1). CF is caused by variants in the cystic fibrosis transmembrane conductance regulator (CFTR) gene that result in the absence or dysfunction of the CFTR protein, a cell-surface chloride channel that regulates salt and water absorption and secretion across cells in multiple organs. This loss of chloride transport leads to the accumulation of thick, tenacious mucus in the bronchi of the lungs, loss of exocrine pancreatic function, impaired intestinal absorption, reproductive dysfunction, and elevated sweat chloride concentration (2).

CF is a progressive, degenerative multi-system disease that mainly affects the lungs and digestive system. Given this underlying disease process, the aim of treatment is to alter the natural history, control symptoms and reduce morbidity associated with recurrent pulmonary exacerbations and hospitalizations. Percent predicted Forced Expiratory Volume in one second (pp%FEV1) is an important measure of lung function in CF (and other lung diseases)(3). Currently, approved medications work in slowing the trajectory of lung function decline and optimizing growth and nutrition. The strategy of CF care is to slow the evolving lung damage and the resultant decline in lung function that ultimately leads to respiratory failure and death.

Since 2012, CFTR modulators have been approved to tackle the underlying defect of CF. Although not a cure, they aim to restore the function of the CFTR protein at the cell surface. CFTR modulators are tailored to work to correct specific CFTR variants and are an example of personalized precision medicine. Consensus guidelines already include CFTR modulator therapies (4). They are recommended as an adjunct to current management, which has historically focused on treating consequences of the defect, because end-organ damage has already occurred and therefore these downstream treatments will likely remain necessary.

With the approval of a new triple therapy modulator, elixacaftor/tezacaftor/ivacaftor (ELX/TEZ/IVA), by Health Canada and its recent recommendation by CADTH (5), it is envisaged that the bulk of Canadian patients with CF will have access to this CFTR modulator. Cystic Fibrosis Canada’s Healthcare Advisory Council has developed this standardized care guideline to support CF clinics in initiating CFTR modulator therapy with the following aims:

1) Indications for starting CFTR modulator therapy
2) Assessing response to CFTR modulator therapy
3) Monitoring patients on CFTR modulator therapy
4) Assessing non-response to CFTR modulator therapy

Current CFTR Modulator treatments
Over the last 15 years, significant research and clinical trials have been undertaken to develop CFTR modulators and to employ them in clinical care. The first modulator commercially available was ivacaftor (IVA; Kalydeco™) which is most effective in patients who have “gating” variants (4% of Canadian CF patients). For this subgroup it is a highly effective medication,
restoring CFTR function with clinical benefits of increasing lung function, reducing hospitalizations and improving nutritional status, and real-world evidence of improving survival and decreasing the need for lung transplant (6,7). In 2021, it was funded both at the 3rd party (i.e. private insurance) and provincial level.

For patients with 2 copies of the most common CF variant, F508del (50% of Canadian CF patients), lumacaftor/ivacaftor (LUM/IVA; Orkambi™) and tezacaftor/ivacaftor (TEZ/IVA; Symdeko™) have been developed. Studies support the efficacy of LUM/IVA and TEZ/IVA, but not to the degree achieved by IVA in patients with gating variants. Despite Health Canada approval these medications are not broadly funded provincially except through a compassionate basis or, in Quebec, through the ‘patient d’exception’ program.

The advent of a fourth CFTR modulator provides a triple combination therapy, known as elexacaftor/tezacaftor/ivacaftor (ELX/TEZ/IVA; Trikafta™). The combination of 2 correctors (TEZ and ELX) results in more effective correction of CFTR function in the F508del variant. Treatment with ELX/TEZ/IVA results in significant clinical improvements in people with only a single copy of the F508del variant (regardless of the variant on the other allele) (8). When ELX/TEZ/IVA is added to standard of care or substituted for TEZ/IVA in patients with 2 copies of F508del, significant improvements in lung function and sweat chloride have been observed (9). Triple combination CFTR modulator therapy will ultimately replace LUM/IVA or TEZ/IVA in most people with 2 copies of the F508del variant and would be indicated for all people with CF with a single F508del variant.

Health Canada has approved four CFTR modulator therapies that act on the CFTR protein:

1. **Ivacaftor** (IVA; Kalydeco™)(10–15)
   IVA is effective in patients with a gating variant (Class III) or conductance variant (R117H 5T or 7T) (Appendix 1). It is a CFTR potentiator, and its action is to increase the amount of time that the CFTR channel is open, thus improving chloride transport.

   **Indication:** CF patients with at least one gating variant or R117H (Appendix 1).
   **Age:** 4 months or older

2. **Lumacaftor/ivacaftor** (LUM/IVA; Orkambi™)(16–19)
   LUM is a corrector of the F508del variant, modifying the conformational deformity and allowing the CFTR protein channel to move to its correct position at the cell surface (trafficking). The CFTR protein is then potentiuated by IVA to keep the channel open longer, allowing chloride transport.

   **Indication:** F508del/F508del
**Age:** 2 years or older

3. **Tezacaftor/ivacaftor (TEZ/IVA; Symdeko™)(20–23)**

Similar to LUM, TEZ is a corrector designed to facilitate proper folding of the defective CFTR protein so it may be transported to the cell surface. It works in combination with IVA, a potentiator of the CFTR protein. TEZ/IVA has comparable efficacy to LUM/IVA, but with fewer drug interactions and fewer reported acute adverse effects.

TEZ/IVA has been trialed in patients homozygous for the *F508del* variant or heterozygous for the *F508del* variant in combination with other *CFTR* variants having some residual function (RF):

**Indication:**
- *F508del/F508del*
- or
- *F508del* in combination with *CFTR* variants having some RF (Appendix 1)

**Age:** 12 years or older

4. **Elexacaftor/tezacaftor/ivacaftor (ELX/TEZ/IVA; Trikafta™)(24–26)**

This triple therapy builds on the combination of TEZ/IVA by the addition of the next generation corrector, ELX. This compound, when used with TEZ/IVA, substantially increases the amount of CFTR protein and CFTR activity at the cell surface. Clinical trials have shown important benefits in patients with at least one *F508del* variant.

**Indication** *F508del* in combination with any other *CFTR* variant (Appendix 1)

**Age:** 6 years or older

Indications for starting CFTR modulator therapy

All Canadians with a confirmed diagnosis of CF should have access to Health Canada-approved CFTR modulators based on their CFTR variants.

The diagnosis of CF requires:
- Clinical symptoms/features or a positive newborn screen and either
  - Two disease-causing CFTR variants
  - Sweat chloride concentration >60 mmol/L (on 2 occasions if only one CFTR variant known).

To be eligible for CFTR modulator therapy, the following will apply:

1. **Mutation:** *F508del/Any CFTR variant or Gating variant/Any CFTR variant or R117H/Any CFTR variant*

   These genotype recommendations are based on Phase 3 clinical trials showing substantial clinical improvement with CFTR modulators and Health Canada approval.

2. **Age:** as approved by Health Canada

   CFTR modulators should be initiated at the **YOUNGEST** age possible with the goal of attenuating disease progression and improving clinical status. Data suggest that early introduction can reverse disease progression, such as restoring pancreatic function(9). There is **NO** data to support withholding CFTR modulators until significant clinical symptoms have developed or a drop in lung function occurs.

3. **Lung function:** No minimum or maximum FEV₁

   In Canada, due to improvements in care, early-stage lung disease in cystic fibrosis, as defined by conventional spirometry measurement, is increasingly not seen until adolescence or in young adults with CF(27). However, FEV₁ is not a useful marker in mild lung disease, in part due to its relatively insensitivity to detection of early small airways destruction (28). This is illustrated when CF patients with no abnormality in lung function underwent chest CT imaging; despite a normal FEV₁, there was evidence of significant structural lung disease (29). Additionally, several trials have shown that in patients with normal lung function (ppFEV₁ >90%) the addition of a CFTR modulator caused further significant gains in ppFEV₁ (12), illustrating improvement to be made in mild CF lung disease. Data from 2021 showed in children aged 6-11 years with an average ppFEV₁ of 89% (of whom 45% had ppFEV₁ >90%), the addition of ELX/TEZ/IVA produced an increase in ppFEV₁ of 10% (24). Consequently, no upper limit of lung function should be required for eligibility as further significant gains in respiratory health can be made in CF patients with mild lung disease.
Patients with lung function that is low (ppFEV₁ <40%) or who are awaiting lung transplantation also have the potential to improve on treatment to the point where many no longer need transplantation (6,30). Consequently, no lower limit of lung function should be required for eligibility.

4. **Pancreatic status:** Pancreatic sufficient and insufficient

Pancreatic status does not affect eligibility. Most patients with CF are pancreatic insufficient but some patients are not. Early introduction of CFTR modulator therapy has the potential to restore pancreatic function (31) or delay onset of pancreatic insufficiency (13,30). In patients with pancreatic sufficiency, CFTR modulators will likely preserve pancreatic function.
Healthcare Advisory Council guidelines for prescribing a CFTR modulator

Table 1 summarizes the four CFTR modulators currently approved by Health Canada. The recommended CFTR variant, age of initiation and duration for each modulator is provided.

Pre-modulator assessment

If a patient has not had a confirmatory sweat test and/or CF genotyping this should be undertaken. Baseline clinical assessments required are illustrated in Tables 2a and 2b. These should be obtained when the patient is clinically stable.

Response to therapy

Clinical trials for CFTR modulators have reported improvements in lung function and weight and reduced pulmonary exacerbations requiring antibiotics. As CFTR modulators are systemic medications they impact CFTR function in the sweat glands as measured by the concentration of chloride in sweat. Although this does not have direct clinical significance at an individual level (other than reducing risk of dehydration or heat stroke), it is a biomarker of the effect of CFTR modulators and trials have shown modulator use is associated with a reduction in sweat chloride.

Longer term follow-up studies have evaluated the impact of CFTR modulators on FEV₁ rate of decline (30,32,33). These studies have shown an improvement in lung function trajectory with a slowing in the rate of FEV₁ decline compared to patients not on CFTR modulators. However, patients may STILL have a decline in FEV₁ over time DESPITE the impact of CFTR modulators (30,32,34). Patients with CF have bronchiectasis with chronic infection and irreversible structural lung damage that will impact FEV₁ recovery and trajectory. There is some evidence emerging to suggest that benefits from therapy may be sustained over time and FEV₁ may not decline in patients on ELX/TEZ/IVA (35,36).

In children under 12 years of age, FEV₁ is often in the normal range despite significant lung disease. A significant change in FEV₁ cannot be expected even in patients who are otherwise experiencing benefit from treatment. It is not a feasible to measure FEV₁ in children under the age of 6 years and efficacy is difficult to assess in this age group due to limited respiratory symptoms.

Modeling and real-life experience with CFTR modulator introduction have shown significant reduction in disease severity and improvement in clinical parameters in patients with significant disease burden (7,37). In addition, patients report an impact on respiratory symptoms, sleep quality, general well-being and physical self-esteem, and a reduced treatment burden. After treatment initiation patients reported renewed and unexpected physical strength leading to greater self-confidence, autonomy, and long-term planning (37).
CF-related co-morbidities should also be considered. Although not reported in clinical trials, patients may experience improvement in CF issues such as sinus disease, pancreatitis, and CF-related diabetes with the introduction of CFTR modulators (38).

Data has suggested that there may be responders and non-responders to CFTR modulator therapy (39). In order to identify responders, the recommendation is to evaluate CFTR modulator therapy for a MINIMUM duration of 1 year. This duration is needed to accurately assess reductions in pulmonary exacerbation frequency, provide adequate lung function data to determine improvement and stabilization of FEV₁ over time, and to monitor improvement in nutrition.

Meaningful clinical responses to be monitored include:

1. Improvement in lung function as measured by FEV₁ or Lung Clearance Index (LCI) (where available) obtained at a time of clinical stability
2. Reduction in the number of pulmonary exacerbations
3. Stabilization in lung function over time (i.e. attenuation of the usual decline in lung function in CF)
4. Reduction or stabilization of respiratory symptoms
5. Improvement in nutritional status
6. Improvement in quality-of-life scores
7. Reduction in sweat chloride.

**Concurrent treatment**

At the present time, all patients commenced on a CFTR modulator should continue with current treatments as directed by their CF clinic (e.g. pancreatic enzymes, mucolytics, inhaled antibiotics, bronchodilators, anti-inflammatory agents). They should continue to be monitored quarterly as per CF standards of care. Ongoing clinical studies will determine what, if any, changes in CF care can be safely incorporated once patients are on CFTR modulator therapy.

The schedule of clinical assessment and monitoring is outlined in Tables 2a and 2b.

**Treatment Response**

It is expected that responders will have at:

**3 months**

1) Absolute improvement in ppFEV\textsubscript{1} of $\geq5\%$, measured at time of clinical stability

or

2) A decrease in sweat chloride by 20% or 20mmol/L from baseline

or

3) Improvement in respiratory symptoms (as measured by CF Questionnaire-Revised (CFQ-R): Respiratory Domain) by $\geq4$ points (i.e. the minimum clinically important difference).

**12 months**

1) No treatment-limiting adverse events or medication safety issues, and one or more of:

2) Reduction in pulmonary exacerbations (IV or oral antibiotic treatment) by 20%

or

3) Stabilization of lung function rate of decline above baseline

or

4) Improvement in nutritional status with normalization of growth and nutrition

or

5) Radiological improvement or stability in chest CT scan.

Table 3 is a summary of changes in expected outcomes for responders to different CFTR modulators.

**Monitoring**

Comprehensive monitoring of patients who are commenced on CFTR modulators is detailed in Tables 2a and 2b. Clinics should aim to follow this schedule in order to demonstrate response to therapy.

**Side effects**

After initiation of CFTR modulators, it is important to focus on safety outcomes and monitor for potential adverse effects (Table 4). A systematic review of safety outcomes reported in real-world studies of the four market-available CFTR modulators has previously been published and is an excellent source of reference, but there are limited reports of longer-term real-world experience, especially with ELX/TEZ/IVA (40). Therefore, vigilant post-market monitoring for both expected and unexpected adverse effects is warranted.
Safety issues of note are:

i) Liver enzymes and/or bilirubin
Elevated transaminases have been observed in patients on CFTR modulators. Isolated elevation in bilirubin can also be seen in some cases. This can occur at any time during treatment, even if the modulator has been previously well tolerated. Rarely does this result in the need to interrupt therapy, reduce the dose, or discontinue the modulator. Elevated transaminases and bilirubin will need to be reviewed to further determine the need to interrupt therapy, reduce the dose, or discontinue the modulator (Table 5). It is recommended that liver enzymes should be monitored one month post-initiation and every three months in the first year, and then at least annually. For individuals with moderate or severe CF-related liver disease, recommendations for dosage adjustments are available (26). Worsening of liver function has been observed in patients with pre-existing cirrhosis and portal hypertension who have started CFTR modulators.

ii) Rash or hypersensitivity reactions
Rash is relatively common following initiation of CFTR modulators and has been reported in real-world studies for each of IVA, LUM/IVA, and TEZ/IVA. Similar incidence was seen in clinical trials, with cases of rash being reported for all four CFTR modulators, and serious rash or discontinuation due to rash being reported for ELX/TEZ/IVA and LUM/IVA. Rare cases of delayed hypersensitivity reactions have also been reported. The incidence of rash events appears to be higher in female CF patients, particularly those on hormonal contraceptives, and more frequent on ELX/TEZ/IVA, but the mechanism behind this is unclear.

Most cases of rash are mild and self-resolve. Few individuals require interruption or discontinuation of therapy for rash or hypersensitivity reactions. In the case that a rash or hypersensitivity reaction does warrant interruption or discontinuation of therapy, after symptoms have resolved, if deemed appropriate, the CFTR modulator may be retried with close monitoring. Desensitization protocols have been published (41–43), and CF centres may have alternate strategies informed by real-world practice.

iii) Drop in ppFEV₁ and worsening respiratory symptoms
Respiratory-related side effects, including chest tightness, dyspnea, and declines in ppFEV₁ have been reported with LUM/IVA but not the other available CFTR modulators. Bronchodilators may be beneficial in mitigating symptoms of chest tightness, wheeze, and increased work of breathing in some individuals. Improvement in or resolution of symptoms typically occurs within 1–4 weeks following initiation, but symptoms and/or ppFEV₁ below baseline could persist beyond this and some patients may require a dose reduction or discontinuation of LUM/IVA altogether to achieve resolution.

iv) GI-related adverse effects
Symptoms of abdominal pain, nausea, and vomiting have been reported in the real-world studies, but rarely prompted discontinuation of therapy. Concerns have been raised about the
potential for distal intestinal obstruction syndrome (DIOS) following initiation of highly effective CFTR modulators. Therefore, patients with chronic constipation and/or other risk factors for DIOS should have their bowel regimen optimized and constipation ruled-out prior to initiation of therapy and be closely monitored following initiation.

v) Blood pressure elevation
Elevations in blood pressure were reported in the phase 3 clinical trials for LUM/IVA and ELX/TEZ/IVA. For ELX/TEZ/IVA, 4% of treated subjects had systolic blood pressure >140 mmHg and 10 mmHg increase from baseline on at least two occasions. Similarly, 1% had diastolic blood pressure >90 mmHg and 5 mmHg increase from baseline on at least two occasions. The mechanism by which CFTR modulators may cause blood pressure elevations remains unclear.

vi) Creatinine kinase
CK elevations have been reported in clinical trials for all four CFTR modulators. Clinical context of elevations is important, as CK levels fluctuate significantly with exercise and physical activity, especially if intensive, and may take a few days to normalize thereafter. Although the clinical relevance of CK elevations is unclear, some cases may be serious enough to warrant interruption or discontinuation of therapy.

vii) Mental health
Cases of negative impacts on mental health (e.g. depression, anxiety) have been reported for all four market-available CFTR modulators, even in individuals without a prior history of mental health concerns, raising a signal for a potential association with CFTR modulators. Although a causal relationship has not been established and a mechanism is not clear, it is an important potential outcome to be mindful of. In addition, there are significant drug-drug interactions with LUM/IVA and antidepressant medications.

viii) Neurological effects
“Brain fog”, fatigue, and/or sleep disturbances have been reported by some individuals initiated on ELX/TEZ/IVA (40). In some cases, adjustments in the ELX/TEZ/IVA dosing regimen may help mitigate symptoms. A potential mechanism for these effects is not clear and a causal relationship cannot be established.

ix) Cataracts
Cases of non-congenital lens opacities have been reported in pediatric patients treated with IVA-containing regimens. Although other risk factors were present in some cases (such as corticosteroid use, exposure to radiation), a possible risk attributable to treatment with IVA cannot be excluded. Baseline and follow-up ophthalmological examinations are recommended in pediatric patients initiating treatment with CFTR modulators: examinations should be done at baseline, 6 months, and on annual basis thereafter until the age of 18 years.
Drug-drug interactions (Figure 1 (44))

It is important to assess for drug-drug interactions when starting or stopping medications in an individual on a CFTR modulator or when transitioning from one CFTR modulator to another. IVA, TEZ, and ELX are substrates of cytochrome P450 (CYP) enzyme CYP3A. Therefore, strong and moderate inhibitors (e.g. azole antifungals) of CYP3A can increase exposure to IVA, TEZ, and ELX, while inducers (e.g. rifampin) can decrease serum levels. Recommendations are available for how to dose-adjust modulators when taken concomitantly with moderate or strong CYP3A inhibitors, but concomitant use with inducers should be avoided\(^{10,16,20,26}\). It is important to note that foods and herbal products can also affect CYP3A (food or drinks containing grapefruit can inhibit CYP3A in the gastrointestinal tract, while the herbal product St. John’s wort induces CYP3A).

CFTR modulators have also been associated with inhibition or induction of enzymes. IVA and one of its metabolites weakly inhibit CYP3A and P-glycoprotein (P-gp), and potentially CYP2C9. Because of the potential impact on CYP3A and CYP2C9, the international normalized ratio (INR) should be closely monitored in individuals on warfarin who are starting or stopping a CFTR modulator. Alternatively, LUM is an inducer of CYP3A and UDP-glucuronosyltransferase (UGT) enzymes, and may increase metabolism of concomitant medications that are substrates of these enzymes (e.g. hormonal contraceptives,azole antifungals, select immunosuppressants, and psychotropic medications). This is an important consideration for patients transitioning from LUM/IVA to either TEZ/IVA or ELX/TEZ/IVA, particularly in patients taking concomitant medications that are substrates of CYP3A and/or UGT. Once LUM/IVA is discontinued and these enzymes are no longer induced, some medications that are substrates of these enzymes may require a decrease in dose to reduce the risk for toxicity. As well, discontinuation of LUM/IVA may broaden the number of appropriate therapeutic alternatives in cases where certain medications were to be avoided due to the inductive effects of LUM (e.g. hormonal contraceptive options for women).

Special considerations for patients receiving IVA, LUM/IVA, or TEZ/IVA

Health Canada approved ELX/TEZ/IVA in June 2021 for CFTR variants \textit{F508del}/Any in patients 12 years and older and in April 2022 for patients 6 years and older. A small number of children will remain on either LUM/IVA or IVA.

Data has shown that ELX/TEZ/IVA has superiority over TEZ/IVA in patients with 2 copies of \textit{F508del} \(^{(9)}\). In a study comparing patients with \textit{F508del}/a minimal function or gating variant who were randomised to either continue taking TEZ/IVA or IVA or switched to ELX/TEZ/IVA, a modest incremental improvement in FEV\(_1\) was observed, with significant gains in CFQ-R: Respiratory domain and further reduction in sweat chloride levels \(^{(45)}\).

All eligible patients on IVA, LUM/IVA or TEZ/IVA, should have the opportunity to transition to the triple therapy combination, ELX/TEZ/IVA. Please see the above important consideration for drug-drug interactions in patients transitioning from LUM/IVA.
Pregnancy/lactation and CFTR modulators

CFTR modulators may increase fertility in women with CF (46,47) due to improvement in clinical status and to their impact on the mucus in the cervix and uterus; therefore, it is important for women who currently on or who are planning to initiate a CFTR modulator to use reliable contraception to prevent unplanned pregnancies. The clinical trials of CFTR modulators excluded women who were not using effective contraception, so the effect of these drugs on a developing human fetus is unknown. Animal studies of the individual drugs IVA, LUM, TEZ and ELX indicate no impact on organogenesis at normal human doses.

CFTR modulators cross the placenta (48) and are expressed in breast milk (49). The potential risks and benefits of taking CFTR therapy during pregnancy and during breast-feeding must be discussed, ideally before pregnancy. Real-world experience is limited, but case reports/series and an international survey have demonstrated that CFTR modulators appear to be well tolerated during pregnancy (50,51). Discontinuation of CFTR modulators has been associated with significant decline in clinical status (52), sometimes warranting re-initiation of therapy in pregnant women who stopped their CFTR modulator during the pregnancy (51). As CFTR modulators have been associated with cataracts in children, it would be advisable that infants born to, and/or breast-fed by, mothers taking CFTR modulators have ophthalmologic examination. A 2021 report reveals the potential for infants with CF born to mothers taking CFTR modulators to falsely test negative for CF in newborn screens. CFTR mutation testing for all infants born to mothers who are on a CFTR modulator during their pregnancies is recommended (53).

CF Patients who have received a lung transplantation

Lung transplant is a treatment option for people with CF with end-stage lung disease. While CFTR modulators would not be expected to directly improve lung graft function, they have the potential to alleviate extrapulmonary manifestations of CF such as chronic rhinosinusitis and gastrointestinal disease. Of note, paranasal sinuses may act as a reservoir for pathogens following transplantation, therefore treatment of chronic rhinosinusitis with CFTR modulators may reduce respiratory infectious complications after lung transplantation (54–57).

With the introduction of ELX/TEZ/IVA, evidence is emerging of its use after lung transplant (58–60). Drug-drug interactions between CFTR modulators and immunosuppressants, such as calcineurin inhibitors, should be expected (61). In addition, liver injury secondary to use of CFTR modulators may complicate management of a lung transplant recipient prescribed antimicrobials and immune suppressing medications associated with hepatotoxicity.

The general recommendations on response to CFTR modulator therapy following initiation would not be applicable to the lung transplant population. It is recommended that a CF specialist be involved in the initiation of CFTR modulators and subsequent monitoring of a CF patient who has undergone lung transplant and commenced on a CFTR modulator.
Discontinuation

Discontinuation (or dose reduction) of CFTR modulator therapy should be considered in patients who have clinically significant adverse effects that persist or recur despite a decrease in dose (if appropriate) and/or stopping and re-challenge.

Examples of these reactions may include:

1. Elevation of transaminases (Table 5) beyond the higher range of fluctuations observed in patients with CF (>8x ULN) or 3x ULN of transaminases and bilirubin (>2x ULN)
2. Allergic reactions to treatment and failed desensitisation challenges

However, the risk-benefit of discontinuing treatment should be considered on a case-by-case basis depending on the severity of the adverse event and risk of stopping treatment.

Therapy should be discontinued in patients who, as assessed by the CF team, do not meet criteria for response to the CFTR modulator or are non-adherent to the CFTR modulator. This decision to discontinue therapy should be done when the patient is clinically stable, and after any confounding co-morbidities have been assessed and non-adherence issues have been addressed.

How to start CFTR modulators

Prior to initiation of a CFTR modulator, it is recommended that patients (and caregivers) receive detailed education and counselling about the therapy as well as all necessary follow-up and monitoring. The appropriate modulator dose based on patients’ age, liver function, and drug-drug interactions should be confirmed prior to initiation (and reassessed, should any of these parameters change). For patients who have had a significant adverse reaction to a CFTR modulator and a rechallenge is deemed appropriate, or if initiating patients at a reduced dose and titrating to full-dose is preferred, potential protocols are summarized in the systematic review performed by Dagenais et al. (40).

No titration or cross-tapering is necessary for patients who are transitioning from one CFTR modulator to ELX/TEZ/IVA. Patients will take the last evening dose of their baseline modulator, then the first dose of ELX/TEZ/IVA the following morning and continue with ELX/TEZ/IVA thereafter. When transitioning from LUM/IVA it may take up to 2 weeks for ELX/TEZ/IVA to have an effect (62).
Summary

The approval of CFTR modulators by Health Canada is a milestone in CF care and is the first time that a CF treatment has targeted the basic defect and not the consequences of the disease. Real-world evidence suggests that CFTR modulators will slow the progression of disease, reduce mortality and improve quality of life. All patients who are eligible should be started on therapy as soon as possible to prevent progression of lung disease and other CF-related co-morbidities.

Patients should be started on an age-appropriate, CFTR variant-specific modulator with a recommended duration of at least 1 year. Response to therapy and safety should be monitored. If response to therapy is seen, then patients will continue indefinitely on the CFTR modulator therapy and other standard of care treatments. Follow up will be determined by their CF clinic. Discontinuation of modulator therapy should be performed in patients who experience significant side effects, are deemed non-responders after 1 year of therapy, or are unable to adhere to therapy and/or the necessary follow-up monitoring despite all available support strategies. Efficacy data should be collected as part of the Canadian Cystic Fibrosis Registry or as part of a prospective study.

Standard for CF Clinic visit &/or recommended by product monograph
Clinical data needed to support CFTR modulator response
May have clinical relevance to CFTR modulator response

<sup>a</sup> LCI to be measured where available at baseline, 3 months and 12 months
<sup>b</sup> If ppFEV₁ <40%, include CPET or 6-minute exercise test at 6 and 12 months
<sup>c</sup> Samples obtained by sputum or cough swab
<sup>d</sup> For patients 6 to 18 years of age and then annually until 18 years, to exclude cataracts. May be performed by optometrist.
<sup>e</sup> For patients aged 12 years and older
<sup>f</sup> Events of special interest: rash, DIOS, pancreatitis, mental health, new organisms isolated in sputum
<sup>g</sup> Review of all prescribed medication including airway clearance

<sup>ALT</sup>, alanine aminotransferase; <sup>AST</sup>, aspartate aminotransferase; <sup>ALP</sup>, alkaline phosphatase; <sup>GGT</sup>, gamma glutamyl transferase; <sup>CBC</sup>, complete blood count; <sup>CFQ-R</sup>, Cystic Fibrosis Questionnaire-Revised; <sup>CK</sup>, creatine kinase; <sup>DIOS</sup>, distal intestinal obstruction syndrome; <sup>GAD-7</sup>, General Anxiety Disorder-7; <sup>LCI</sup>, lung clearance index; <sup>PHQ-9</sup>, Patient Health Questionnaire-9

OR
Cystic fibrosis (CF) patients aged 18 years and older who have at least one copy R117H

Lumacaftor/Ivacaftor (Orkambi™)
Cystic fibrosis (CF) patients who are homozygous for the F508del variant in the cystic fibrosis transmembrane conductance regulator (CFTR) gene.

Tezacaftor/Ivacaftor (Symdeko™)
Cystic fibrosis (CF) in patients who are homozygous for the F508del variant

OR

| Heterozygous for F508del and: |
|-----------------------------|-----------------|----------------|
| P67L                        | A455E           | R1070W         |
